0.01		Explain the need of non conventional energy sources		CO	10
Q.01	a	Explain the need of non conventional energy sources	L2	CO	10
				1	
		The need for non-conventional energy sources arises from			
		several critical factors that highlight the limitations and			
		challenges associated with traditional energy sources,			
		particularly fossil fuels. Here are some key reasons:			
		1. Depletion of Fossil Fuels: Oil production is expected			
		to gradually decline after reaching its peak around 2015,			
		with most of the world's oil reserves potentially being			
		depleted by the end of this century. This decline poses a			
		significant risk to energy security, as oil currently meets			
		about 30% of global energy demand and powers most			
		transportation systems.			
		cransportation systems.			
		2. Environmental Concerns: Conventional energy			
		sources, especially fossil fuels, contribute to environmental			
		degradation, including air pollution and greenhouse gas			
		emissions. Non-conventional energy sources, such as solar			
		and wind, are much cleaner and have a lower			
		environmental impact, making them more sustainable			
		options for the future.			
		3. Economic Viability: As fossil fuel resources become			
		scarcer, the costs associated with extraction and production			
		are likely to rise. Non-conventional energy sources, while			
		initially requiring investment in technology and			
		infrastructure, can ultimately lead to lower operational			
		costs and greater energy independence.			
		4. Diverse Energy Portfolio: Relying solely on fossil

			<b>411</b>	E052
	fuels makes energy systems vulnerable to market fluctuations and geopolitical tensions. Incorporating non-conventional energy sources into the energy mix can enhance energy security and resilience.			
	5. Technological Advancements: Innovations in technology are making non-conventional energy sources more efficient and economically feasible. For instance, advancements in solar panel technology are improving energy capture and reducing costs, making solar energy a more attractive option.			
	6. Sustainability: Non-conventional energy sources, such as solar, wind, and hydroelectric power, are derived from natural processes that are continuously replenished. This sustainability is crucial for meeting current and future energy needs without depleting resources.			
	7. Global Energy Demand: The global demand for energy is expected to continue rising, driven by population growth and economic development. Non-conventional energy sources have the potential to meet this demand sustainably and indefinitely.			
b	Explain merits and demerits of any three non conventional energy Sources	L2	CO 1	10
	Sure! Let's explore the merits and demerits of three non- conventional energy sources: solar energy, wind energy, and geothermal energy.			
	<ul><li>1. Solar Energy</li><li>Merits:</li><li>Abundance: Solar energy is incredibly abundant. The</li></ul>			
	Earth receives about $1.8 \times 10^{11}$ megawatts (MW) of solar power, which is thousands of times greater than the current consumption rate of all commercial energy sources.  - Environmentally Friendly: It is a clean energy source,			
	producing no harmful emissions during operation, which helps combat climate change.  - Sustainability: Solar energy is renewable and can meet			
	current and future global energy needs indefinitely, as long as the sun shines.  Demerits:			
	- High Initial Costs: The installation of solar panels and systems can be expensive, which may deter some users.			
		ΟΙΝ WΗΔΤςΔΕ		

- Intermittency: Solar energy generation is dependent on sunlight, which varies by time of day and weather conditions, necessitating energy storage solutions that can add to costs.
- Space Requirements: Large areas are often needed for solar farms, which can be a limitation in densely populated regions.

### 2. Wind Energy

#### Merits:

- Renewable and Sustainable: Wind energy is derived from natural wind currents and is inexhaustible as long as the sun shines and the Earth rotates.
- Low Operating Costs: Once a wind turbine is installed, the cost of operation and maintenance is relatively low compared to fossil fuels.
- Minimal Environmental Impact: Wind energy generation produces no emissions, making it a clean alternative to fossil fuels.

#### **Demerits:**

- Intermittency: Wind energy is also variable, as it depends on wind speed and direction, which can change unpredictably.
- Noise and Aesthetic Concerns: Wind turbines can produce noise and may be considered unsightly by some communities, leading to opposition against new installations.
- Impact on Wildlife: Wind farms can pose threats to birds and bats, which may collide with turbine blades.

## 3. Geothermal Energy

#### Merits:

- Reliable and Consistent: Geothermal energy provides a stable and continuous power supply, as it is not dependent on weather conditions.
- Low Emissions: It has a much lower carbon footprint compared to fossil fuels, contributing to reduced greenhouse gas emissions.
- Small Land Footprint: Geothermal plants require less land compared to solar or wind farms, making them suitable for areas with limited space.

#### Demerits:

- Location Specific: Geothermal energy is site-specific, meaning it can only be harnessed in areas with suitable geological conditions, such as near tectonic plate boundaries.

CO

CO

CO4

10

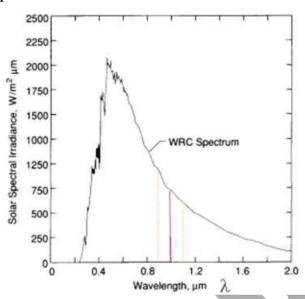

L2

- High Initial Costs: The drilling and exploration required to access geothermal resources can be expensive and risky.

  Potential for Induced Seismicity: There is a ri
- Potential for Induced Seismicity: There is a risk of inducing small earthquakes during the extraction process, which can raise concerns among local communities.

OR

Q.02 | a | Explain spectral distribution of extra-terrestrial radiation

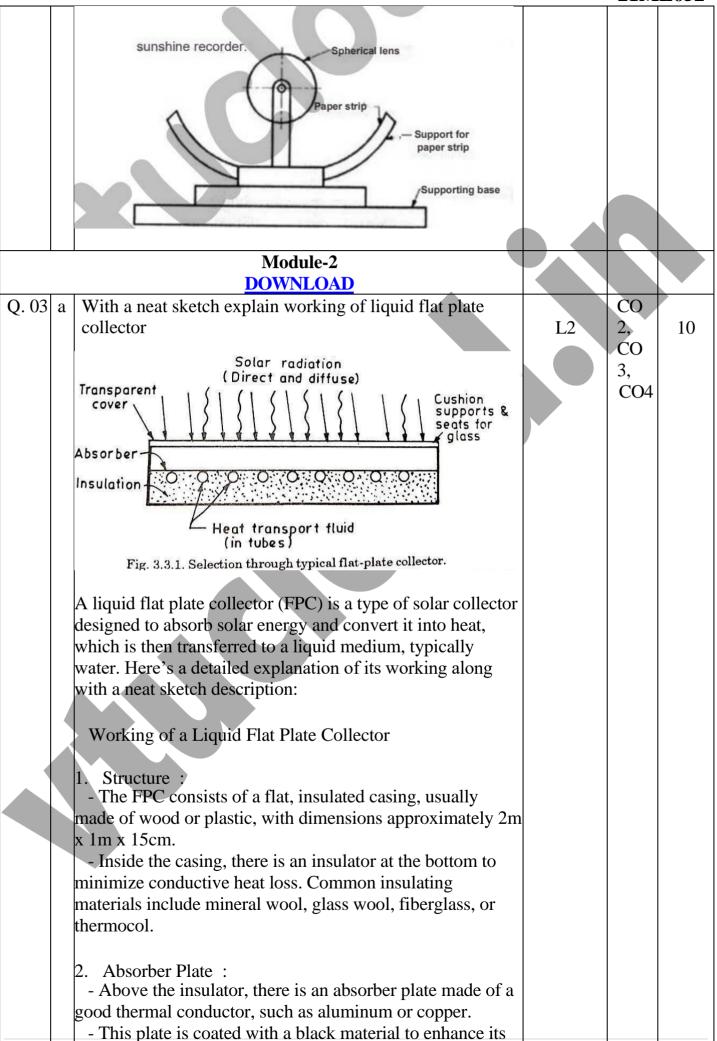

The spectral distribution of extra-terrestrial radiation refers to the way solar radiation is distributed across different wavelengths as it reaches the outer edge of Earth's atmosphere. This radiation is primarily emitted by the sun and spans a wide spectrum, ranging from approximately 0.1 to 4.0 micrometers (µm).

At the top of the atmosphere, the average extraterrestrial irradiance is about 1367 W/m², although this value can vary by  $\pm 3\%$  as the Earth orbits the sun. The sun emits a significant amount of its energy in the ultraviolet (UV), visible, and infrared (IR) regions of the spectrum. Specifically, about 7% of the sun's emission falls within the UV range (0.1 to 0.4  $\mu$ m), while approximately 44% is in the visible light range (0.4 to 0.71  $\mu$ m), and the remaining 48% is in the infrared range (0.71 to 4.0  $\mu$ m).

The solar constant, which is a measure of the flux density of solar energy received per unit area at the mean distance of the Earth from the sun, is crucial for understanding this distribution. It is defined as the amount of solar energy received in unit time on a unit area perpendicular to the sun's rays. The standard value for the solar constant was revised to 1367 W/m² based on measurements taken after 1970.

As solar radiation travels through the atmosphere, it undergoes absorption and scattering, which affects the intensity and spectral distribution of the radiation that ultimately reaches the Earth's surface. Absorption primarily occurs due to gases like ozone and water vapor, while scattering is caused by both gaseous molecules and particulate matter in the atmosphere. This results in a complex interplay of direct and diffuse radiation that is critical for various applications, including solar energy utilization.		
b Explain with neat sketch working of sun shine recorder	L2 CO2, CO 3, CO 4	10

21ME652 ability to absorb solar radiation. The black coating is often applied through chemical treatment, and selective coatings may be used to maximize absorption while minimizing thermal emission. 3. Absorber Tubes: - The underside of the absorber plate features absorber tubes that run along its length. These tubes are also made of the same material as the absorber plate. - A heat-absorbing medium, typically water, circulates through these tubes. As solar radiation heats the absorber plate, the water in the tubes absorbs this heat, causing its temperature to rise. 4. Glass Cover: - A transparent glass cover is placed above the absorber plate. This cover serves to create a greenhouse effect, allowing solar radiation to enter while reducing heat loss through convection and radiation. Heat Transfer : - The heated water is then collected and can be used for various applications, such as space heating, domestic hot water supply, or even in industrial processes. 		drying and cooking, utilizing various technologies that capitalize on the sun's heat.			
		Solar Drying: Solar drying involves using sunlight to remove moisture from food or other materials, which helps in preservation. This method is particularly beneficial in regions with abundant sunlight. The process typically involves placing the items to be dried in a solar dryer, which can be a simple structure that captures and retains heat. The heat from the sun warms the air inside the dryer, which then circulates around the items, evaporating moisture. This method is energy-efficient and can significantly reduce the time and cost associated with traditional drying methods.  Solar Cooking: Solar cookers utilize sunlight to cook food, offering a sustainable alternative to conventional cooking methods that rely on fossil fuels or electricity. There are several types of solar cookers:			
		1. Box Cookers: The simplest form, first developed by Horace de Saussure in 1767, consists of an insulated box with a transparent lid. These cookers can reach temperatures between 50°C to 100°C and can be used even on partially cloudy days.			
		2. Concentrating Solar Cookers: These use reflectors to focus sunlight onto a cooking pot, achieving higher temperatures (up to 350°C). Common designs include flat plate, disc, and parabolic trough types. For instance, the Solar Kitchen in Auroville, India, employs a unique solar bowl technology that uses a fixed spherical reflector to track the sun, allowing it to cook up to 2,000 meals daily at temperatures around 150°C.			
		Both solar drying and cooking not only reduce fuel costs and reliance on traditional energy sources but also contribute to improved air quality by minimizing smoke emissions. These methods are particularly advantageous in rural areas where access to conventional energy sources may be limited. Overall, solar energy provides a versatile and eco-friendly solution for food preparation and preservation.

Q.04	a	Explain Sensible Heat and Latent Heat Thermal Energy Storage	L2	CO2, CO 3,	10
		07082024	OIN WHATSAF	P CHANI	<u>NEL</u>

CO 4

Sensible heat and latent heat are two important concepts in thermal energy storage, particularly in systems that utilize solar energy.

Sensible Heat refers to the thermal energy that causes a change in the temperature of a substance without altering its phase. For example, when water is heated, its temperature rises as energy is added. This energy is known as sensible heat. In thermal energy storage systems, materials such as water or rocks can store sensible heat. The amount of sensible heat stored is determined using the following formula:

 $Q=mc\Delta TQ=mc\Delta T$ 

#### Where:

- QQQ is the heat energy stored (in joules),
- mmm is the mass of the substance (in kilograms),
- ccc is the specific heat capacity of the substance (in joules per kilogram per degree Celsius),
- $\Delta T \setminus Delta T \Delta T$  is the change in temperature (in degrees Celsius).

This method of storage is straightforward and efficient, allowing for the direct use of the stored heat energy when required.

Latent Heat, in contrast, is the thermal energy absorbed or released by a substance during a phase change, such as melting, freezing, vaporization, or condensation, without any change in temperature. For instance, when ice melts to form water, it absorbs heat, known as the latent heat of fusion, but its temperature remains constant until all the ice has melted. In thermal energy storage systems, materials that undergo phase changes, known as phase change materials (PCMs), can store substantial amounts of energy. The energy stored during a phase change is calculated

using the formula:

Q=mLQ=mLQ=mL

Where:

- QQQ is the heat energy stored (in joules),
- mmm is the mass of the substance (in kilograms),
- LLL is the latent heat of the substance (in joules per kilogram).

This method is particularly advantageous because it allows energy to be stored and released at a constant temperature, making it ideal for applications such as heating and cooling systems.

b Explain the working principle and I-C Characteristics of Solar PV Cell

Charge Controller Inverter DC/AC House

The working principle of a solar photovoltaic (PV) cell is based on the photovoltaic effect, which allows the conversion of solar energy directly into electrical energy. Here's a detailed breakdown of how it works:

- 1. Structure of the Solar Cell: A typical solar cell is made from semiconductor materials, most commonly silicon. Silicon has four valence electrons, which makes it a semiconductor. When impurities such as phosphorus or boron are added to silicon, it creates free electrons or holes, respectively, enhancing its conductivity.
- 2. Absorption of Solar Energy: When sunlight (photons) strikes the solar cell, it is absorbed by the semiconductor material. This energy excites the electrons, giving them enough energy to break free from their atomic bonds, creating free electrons.
- 3. Electric Field Creation: The solar cell is designed with a built-in electric field, typically created by the junction of p-type (positive) and n-type (negative) silicon. This electric field pushes the free electrons towards the n- type layer and the holes towards the p-type layer, creating a flow of electric current.

L2 CO 2, CO

CO 3.

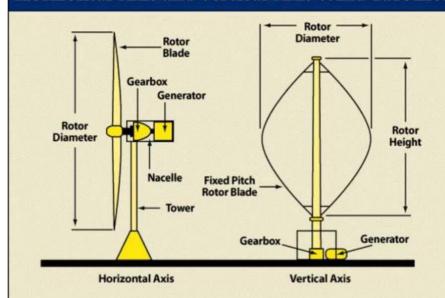

10

CO4

4. Current Generation: The movement of these free electrons constitutes an electric current. When the solar cell is connected to an external load (like a battery or an inverter), this current can be harnessed to power electrical devices.  5. I-V Characteristics: The current-voltage (I-V) characteristics of a solar PV cell describe how the current output varies with the voltage across the cell. The key points on the I-V curve include:  - Open Circuit Voltage (Voc): The maximum voltage available from a solar cell when no current is flowing (the circuit is open).  - Short Circuit Current (Isc): The maximum current that flows when the output terminals are shorted (the voltage is zero).  - Maximum Power Point (MPP): The point on the I-V curve where the product of current and voltage is maximized, representing the optimal operating condition for the solar cell.  The efficiency of a solar cell, which is typically between 10% to 20%, indicates how much of the solar energy is converted into usable electrical energy. Factors such as temperature, angle of sunlight, and shading can affect the performance and I-V characteristics of the solar cell.  Module-3  DOWNLOAD  Q. 05 a List types of wind mills. (VAWTs). Let's focus on the Horizontal Axis Wind				

Machine.

### Horizontal-Axis and Vertical-Axis Wind Turbines

Horizontal Axis Wind Turbines (HAWTs)

### Characteristics:

- Rotor Axis: The rotor axis is horizontal and parallel to the wind direction. This design is the most prevalent for large-scale wind turbines.
- Blades: HAWTs typically feature two or three blades mounted on a horizontal shaft. These blades are aerodynamically designed to optimize performance and efficiency, allowing them to capture wind energy effectively.
- Orientation: HAWTs are equipped with a yaw mechanism that enables the turbine to turn and face the wind direction, maximizing energy capture.

## Advantages:

- Efficiency: HAWTs are known for their high efficiency in converting wind energy into electricity. On average, they can convert about 40% of the kinetic energy in the wind into electricity, with some advanced models achieving conversion rates of up to 50%.
- Power Generation: They are capable of generating significant amounts of power, making them suitable for large-scale wind farms and utility-scale power generation.
- Established Technology: HAWTs are wellestablished with a wealth of operational data and improvements over time, which contributes to their reliability.

## Disadvantages:

Complexity: The design of HAWTs requires a

Q. 06 a With neat explain Fixed dome biogas plant

CO<sub>2</sub>

10

A Fixed-Dome Biogas Plant is a type of biogas production facility designed to convert organic materials, such as animal manure and agricultural residues, into biogas through anaerobic digestion. Here's a detailed explanation of its components, features, advantages, and disadvantages:

# Advantages

- Low Construction Cost: Compared to other biogas plant designs, the Fixed-Dome system is relatively inexpensive to build.
- Minimal Maintenance: Once constructed, these plants require less ongoing maintenance, making them suitable for small-scale operations.

## Disadvantages

- Limited Capacity for Gas Storage: The fixed structure means that it can only store a limited amount of gas, which may not be sufficient for larger operations.
- Complexity in Operation: While the construction is simple, the operational management can be more complex, requiring careful monitoring of the digestion process.

Applications Fixed-Dome Biogas Plants are particularly beneficial for: - Agricultural Operations: Farms can utilize this technology to manage animal waste while generating energy for their operations.			
- Rural Communities : Small communities can benefit			
from self-sufficient energy systems, reducing reliance on			
external energy sources.			
List the applications of biogas. What are the problems involved in production of biogas.	L2	CO 2, CO	10
Biogas has a variety of applications, including:		3, CO4	
1. Electricity Generation: Biogas can be burned in			
engines or turbines to produce electricity, which can be fed			
into the power grid or used in standalone generators,			
especially in rural areas.			
2. Heat Production: It can be utilized for heating			
purposes in industrial processes, residential heating, or combined heat and power (CHP) systems, where both heat			
and electricity are generated simultaneously.			
and electricity are generated simultaneously.			
3. Vehicle Fuel: Biogas can be processed into			
compressed biogas (CBG) and used as a renewable fuel for			
specially designed vehicles, such as buses and trucks.			
4. Waste Treatment: Biogas production helps manage			
organic waste, reducing the need for landfills and			
providing a solution for municipal solid waste, agricultural			
waste, and wastewater treatment.			
5 Fortilizer Droduction . The solid has not dead for me			
5. Fertilizer Production: The solid by-product from			
biogas production, known as digestate, is rich in nutrients			
and can be used as a natural fertilizer or soil conditioner, enhancing soil fertility.			
childrening soft fertility.			
6. Industrial Applications: Biogas can provide process			
heat for industries like food processing, brewing, and paper			
manufacturing, and can also serve as a feedstock for			
producing chemicals and other industrial products.			
However, there are several problems associated with the			
production of biogas:			
1 Foodstook Variability and Quality . The quality and			
1. Feedstock Variability and Quality: The quality and		<u> </u>	

		21111	E034
composition of feedstock can vary significantly, which			
affects the efficiency of biogas production.			
affects the efficiency of blogas production.			
2. Initial Cost: The setup and operational costs for			
biogas plants can be high, posing a financial barrier to			
implementation.			
impromentation.			
3. Technical Complexity: Biogas production requires			
careful management and monitoring, which can be			
challenging and resource-intensive.			
4. Space Requirements: Larger biogas plants need			
significant space for digesters and storage, which can be a			
limitation in certain areas.			
5 Energy Logg - Come methods of his ass are assistant			
5. Energy Loss: Some methods of biogas processing,			
such as compression and liquefaction, can involve energy			
losses, necessitating efficient storage solutions to			
minimize these losses.			
6. Regulatory Compliance: Adhering to local and			
international safety and environmental regulations is			
essential, which can add to the complexity and cost of			
biogas production.			
7. Public Education: Insufficient public education and			
awareness can hinder the adoption and support of biogas			
technologies, impacting community acceptance.

Q. 07 a How are hydroelectric power plants classified? Explain		CO	
power prairie crassifica : Emplain	L2		10
	LZ	2,	10
Hydroelectric power plants are classified based on several		CO	
criteria, primarily focusing on the availability of water flow		3,	
		CO4	
and the height of the water head. Here's a detailed		CO4	
breakdown:			
1 Asserting to the extent of the City of t			
1. According to the extent of water flow regulation:			
- Run-off River Power Plants without Pondage: These			
plants do not have any storage facility. They generate			
electricity only when water is available from the river,			
making them unsuitable for constant, steady loads.			
- Run-off River Power Plants with Pondage: These			
	I		
plants include a storage pond that allows for some		l	
regulation of water flow. They can handle fluctuating loads and are more reliable than those without pondage, suitable			

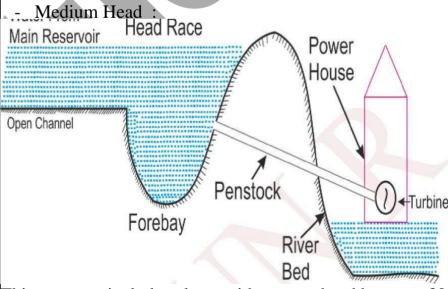

for both base and peak load periods.

- Reservoir Power Plants: These are the most common type of hydroelectric plants. They store water behind a dam, ensuring a consistent water supply throughout the year, even during dry seasons. This type is highly efficient and can meet both base and peak load demands.
- 2. According to the availability of water flow (water head):

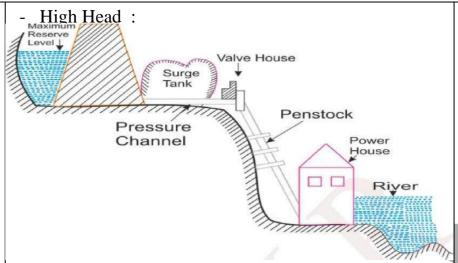

- Low Head:

Defined as having a water head of less than 30 meters. These plants typically use Francis, Kaplan, or propeller turbines and require dam construction to create the necessary water head.

This category includes plants with a water head between 30 meters and 300 meters. They can utilize similar turbine types as low head plants but are designed to operate efficiently at higher elevations.

These plants have a water head greater than 300 meters. They are often more efficient due to the greater potential energy available from the higher elevation.

- 3. According to the types of load supply
- a. Base Load
- b. Peak Load
- c. Pumped storage plants for the peak load
- a. Base load hydroelectric power plant
  This is a large capacity power plant. This plant work as a
  base portion of load curve of power system, that's why it is
  called base load plants. Base load plant is suitable for
  constant load. Load factor of this plant is high and it is
  performed as a block load. Run off river plants without
  pondage and reservoir plants are used as base load plants.
- b. Peak load hydroelectric power plant
  This plant is suitable for peak load curve of power system.
  When demand is high, this type of plant does their job very
  well. Run off river plants with pondage can be employed as
  peak load plants. If water supply is available, it generates
  large portion of load at a peak load period. It needs huge
  storage area. Reservoir plants can be used as peak load
  plants. This type of plant can serve power throughout the
  year.
- c. Pumped storage hydroelectric power plant for the peak load

This is unique design of peak load plants. Here two types of water pond is used, called upper head water pond and tail water pond. Two water ponds are connected each other by a penstock. Main generating pumping plant is lower end. During the off load period, surplus energy of this plant is utilized to pumping the lower head pond water to upper head pond water. This extra water is used to generate

# 21ME652

energy at pick load periods. By doing this arrangement,			
same water is used again and again. Extra water is required only to take care of evaporation and seepage.			
only to take care of evaporation and seepage.			
one of the polation and boopage.			
b Explain the following	L2	CO	10
		2,	
	<u> </u>	∠,	

	211	ME652
(i) Hydrograph	CO	
(ii) Flow Duration Curve (iii) Surge Tank	3, CO	)
(iv) Spill way (v) Draft tube	4	
(i) Hydrograph : A hydrograph is a graphical		
representation that shows the flow of water in a river or stream over a specific period of time. It typically plots		
discharge (the volume of water flowing per unit of time) against time. Hydrographs are essential for understanding		

(ii) Flow Duration Curve: The flow duration curve is a graphical representation that shows the relationship between the flow rate of a river and the percentage of time that flow is equaled or exceeded over a specified period. This curve helps in assessing the availability of water for hydroelectric power generation, as it indicates how often certain flow rates occur, which is vital for optimizing the operation of a hydroelectric plant.

the variability of water flow, which is crucial for managing water resources, designing dams, and planning for flood

control.

- (iii) Surge Tank: A surge tank is a small reservoir located near a hydroelectric power plant, designed to absorb sudden changes in water pressure within the penstock. When there is a sudden reduction in load on the turbine, the surge tank helps to prevent pressure surges (water hammer) that could damage the penstock. It also provides additional water when there is an increase in demand, ensuring a stable flow to the turbines
- (iv) Spillway: A spillway is a structure built into a dam that allows excess water to flow out of the reservoir safely. It is crucial for preventing overflow and potential damage to the dam during periods of heavy rainfall or snowmelt. Spillways can be designed as open channels or gates that can be controlled to manage water levels in the reservoir.
- (v) Draft Tube: A draft tube is a conduit that connects the turbine to the tailrace (the area where water exits the turbine). Its primary function is to recover some of the kinetic energy of the water exiting the turbine, converting it back into pressure energy. This helps to improve the overall efficiency of the hydroelectric power plant by

Q. 08 a		T 0	CO	10
	tidal power plant	L2	2,	10
	Textone		CO 3,	
	tigh tide generator Tidal basin		CO	
	Tidal 4		4	
	basin			
	low tide TG -			
	Flood tide - Flob tide			
	THE STATE OF THE S			
	A tidal power plant can be designed in various			
	configurations, with single basin and double basin systems			
	being two common types. Let me explain both in detail:			
	Single Basin Tidal Power Plant			
	A single basin tidal power plant typically consists of a dam-			
	like structure built across an estuary or bay. This design			
	captures the potential energy created by the difference in			
	water height (head) between high and low tides within a			
	single enclosed area. Here's how it works:			
	1. Mechanism: The plant has sluice gates that open and			
	close to allow water to flow in and out of the basin during			
	high and low tides. When the tide rises, water flows into			
	the basin, and when it recedes, the water is released back into the sea, turning turbines to generate electricity during			
	both phases.			
	our priuses.			
	2. Advantages:			
	- Predictable Energy Generation: The energy output is			
	highly predictable due to the regular tidal patterns.			
	- Flood Protection: It can provide flood protection to			
	the surrounding areas.			
	- High Energy Output: It can generate a significant			
	amount of electricity.			
	3. Challenges:			
	- High Initial Costs: The construction of the barrage			
	and associated infrastructure can be expensive.			

		<u></u>	E052
- Environmental Impact: There can be significant ecological disruptions in the estuarine ecosystems, affecting local wildlife and communities.			
Double Basin Tidal Power Plant A double basin tidal power plant, often referred to as a tidal lagoon, involves two separate basins (high lagoon and low lagoon) that work together to harness tidal energy more efficiently. Here's how it operates:			
1. Mechanism: Similar to the single basin system, but it creates two distinct areas. Water flows between the two lagoons through turbines, generating power from both incoming and outgoing tides. The design allows for more controlled water flow and energy generation.			
<ul> <li>2. Advantages:</li> <li>Less Environmental Impact: Compared to single basin systems, double basin plants can have a reduced ecological footprint.</li> <li>Scalability: They can be built to scale, allowing for</li> </ul>			
larger energy outputs.  - Recreational and Conservation Benefits: The lagoons can provide recreational areas and support local biodiversity.			
<ul> <li>3. Challenges:</li> <li>- High Construction Costs: Like single basin systems,</li> <li>the initial investment can be substantial.</li> <li>- Site-Specific Feasibility: The effectiveness of a</li> </ul>			
double basin system is highly dependent on the geographical location and tidal range.			
b List advantages and disadvantages of Tidal energy  Advantages of Tidal Energy:  1. Predictability: Tidal patterns are highly predictable,	L2	CO 2, CO 3,	10
providing a reliable source of energy.  2. Longevity: Tidal energy systems can have long operational lifespans, often exceeding 100 years.  3. Low Operating Costs: Once installed, the operating		CO4	
<ul><li>and maintenance costs are relatively low.</li><li>4. Significant Power Generation: Tidal barrages can generate a substantial amount of power and also provide</li></ul>			
flood protection and act as bridges.  5. Less Intrusive to Marine Life: Compared to other energy methods, tidal energy installations are generally less intrusive to marine ecosystems.			
	ΝΝ ΜΗΔΤςΔΡΙ	CLIANINI	

	6. Bilateral Energy Production: Tidal systems can			
	generate electricity during both rising and falling tides,			
	providing two periods of energy production each day.			
	7. Environmental Benefits: Tidal energy has negligible			
	greenhouse gas emissions during operation.			
	Disadvantages of Tidal Energy:			
	1. High Initial Costs: The construction of tidal energy			
	systems, particularly barrages, requires substantial capital			
	investment.			
	2. Site Specificity: Tidal energy can only be			
	economically recovered in locations where the tidal range is			
	5 meters or more.			
	3. Variable Energy Availability: The availability of tidal			
	energy is variable, leading to fluctuating power generation.			
	gy as an array as a massage power government			
	4. Environmental Impact: Tidal installations can affect		-	
	-			
	marine ecosystems, fish migration patterns, and sediment			
	transport, necessitating careful site selection and			
	environmental impact assessments.			
	5. Maintenance Challenges: Marine environments are			
	harsh, leading to higher maintenance costs due to corrosion			
	and biofouling.			
	6. Geographical Limitations : Suitable locations for tidal			
	power installations are limited to regions with significant			
	tidal ranges and strong tidal currents.

Q. 09	a What is the basic principle of OTEC		CO	
,		L2	2,	10
	Ocean Thermal Energy Conversion (OTEC) is based on	22	CO	10
	harnessing the temperature difference between the warm		3,	
	surface water of the ocean and the cold water from the		CO4	
	depths. This temperature gradient results from solar energy			
	heating the ocean's surface.			
	The OTEC process unfolds in several stages:			
	1 Warm Surface Water . Warm water tymically between			
	1. Warm Surface Water: Warm water, typically between			
	25°C and 30°C, is pumped from the surface through a heat			
	exchanger. Here, it heats a working fluid with a low			
	boiling point, such as ammonia or a refrigerant.			
	2. Evaporation: The working fluid evaporates into gas			
	due to the heat from the warm water. This gas expands and			
1	drives a turbine connected to a generator, producing	ILLUMENT NEW TOTAL NEW TOT	CHANN	EI
	JC	m $m$ $m$ $m$ $m$	CITAINN	LL

electricity. 3. Cold Deep Water: Cold water is drawn from depths of about 1000 meters, where the temperature is around 4°C to 5°C. This cold water is used to cool and condense the vapor of the working fluid back into a liquid. 4. Recirculation: The condensed working fluid is recirculated back to the evaporator to repeat the cycle. This system allows for continuous and stable energy generation, making it a base-load energy source, unlike other renewable sources that depend on weather conditions. However, OTEC faces challenges such as high initial costs, technical complexities, and environmental concerns. b | Explain with a sketch, the Open Rankine Cycle OTEC CO<sub>2</sub>. **System** CO 10 3. CO Hot Water Hot water 4 pump Evaporator 3 Alternator Work pump Turbine 4 1 Condenser Cold water Cold Water pump The Open Rankine Cycle OTEC (Ocean Thermal Energy Conversion) system is an innovative technology that utilizes the temperature difference between warm surface seawater and cold deep seawater to generate electricity. Here's a detailed explanation along with a sketch description: Open Rankine Cycle OTEC System 1. Warm Surface Seawater: The process begins with warm seawater, typically around 25°C to 30°C, being

pumped into a vacuum chamber. This chamber is crucial as it allows the seawater to vaporize at lower temperatures due to the reduced pressure.  2. Vaporization: In the vacuum chamber, the warm seawater is vaporized, creating steam. This steam is the working fluid that will drive the turbine.  3. Turbine: The generated steam expands and drives a turbine connected to a generator. As the turbine spins, it converts the thermal energy of the steam into mechanical energy, which is then transformed into electrical energy by the generator.  4. Condensation: After passing through the turbine, the steam enters a condenser where it is cooled by cold deep seawater, typically drawn from depths of around 1000 meters, where the temperature is about 4°C to 5°C. The cold seawater absorbs heat from the steam, causing it to condense back into liquid water.  5. Recirculation: The condensed working fluid (now liquid seawater) is then pumped back into the vacuum chamber to repeat the cycle. This pump increases the pressure of the liquid, preparing it to absorb heat again in the next cycle.  Advantages of Open Rankine Cycle OTEC  Desalination: One of the significant benefits of this system is that it can produce fresh water as a byproduct, which is particularly beneficial for arid regions.  Sustainability: If generates clean energy without burning fossil fuels, contributing to reduced greenhouse gas emissions. Hot Dry Rock (HDR)  L2  CO 3, CO	OR			
		L2	CO 3,	10

Geothermal Energy System using Hot Dry Rock (HDR) is an innovative approach to harnessing geothermal energy from the Earth's interior. Here's a detailed explanation along with a description of a neat sketch you can visualize:

Explanation of the Geothermal Energy System:

- 1. Heat Source: The system relies on the heat stored in the Earth's crust, specifically in the HDR, which is heated by the Earth's internal processes.
- 2. Hydraulic Fracturing: To utilize HDR, hydraulic fracturing is employed to create pathways for water to flow through the rock. This process enhances the permeability of the rock, allowing for efficient heat exchange.
- 3. Heat Extraction: Water is injected into the HDR, where it absorbs heat from the surrounding rock. The heated water then rises through the production well to the surface.
- 4. Electricity Generation: At the surface, the hot water or steam is used to drive a turbine connected to a generator, converting thermal energy into electrical energy.

		INIE052
5. Sustainability: The cooled water is then reinjected back into the HDR layer through the reinjection well, ensuring that the system remains sustainable and can continuously produce energy.		
Advantages - Advantages : HDR systems can provide a continuous		
and reliable source of renewable energy, reducing dependence on fossil fuels and lowering greenhouse gas emissions.		
b List and explain the problems associated with Geothermal System operations	L2 2	10
The problems associated with geothermal system operations are diverse and can impact both the economic viability and environmental sustainability of these projects. Here are some of the main challenges:	3.	CO4
1. High Initial Costs: The development of geothermal power plants requires significant investment in exploration, drilling, and construction of the plant. These high upfront costs can be a barrier to entry for new projects and limit investment in this technology.		
2. Site Specificity: Geothermal resources are geographically specific, meaning that not all locations have accessible and economically viable geothermal resources. This limits the applicability of geothermal energy to certain regions, typically those with high geothermal activity, such as volcanic areas or tectonic plate boundaries.		
3. Environmental and Structural Risks: The extraction of geothermal energy can lead to issues such as land subsidence, induced seismicity (earthquakes), and the release of trace gases from geothermal reservoirs. These risks must be carefully managed to minimize their		
<ul> <li>4. Resource Depletion: If not managed properly, geothermal resources can become depleted or experience a decline in productivity over time. It is crucial to implement sustainable management practices to prevent the overexploitation of these resources.</li> </ul>		
5. Geographical Limitations: Effective geothermal energy production is often restricted to regions with high	DIN WHATSAPP CH	

geothermal activity. This means that many areas, especially those not near volcanoes or tectonic plate boundaries, may not be viable for geothermal energy development.		

Bloom's Taxonomy Level: Indicate as L1, L2, L3, L4, etc. It is also desirable to indicate the COs and POs to be attained by every bit of questions.
